

LOFAR Unified Calculator for Imaging (LUCI)¹

The LOFAR Unified Calculator for Imaging, or LUCI, is a unified web interface that allows users to compute several parameters relevant for planning an interferometric observation with LOFAR. The web interface can be accessed at <https://support.astron.nl/luci>. A similar tool for planning beamformed observations is under development.

LUCI is developed and maintained by the SDC Operations group (SDCO) at ASTRON. The source code is publicly available on GitHub at <https://github.com/scisup/LOFAR-calculator>. For comments and/or feature requests, please contact the SDCO group using the [JIRA Helpdesk](#).

For a given observation and pipeline setup, the web interface allows users to

- compute the raw and processed data size,
- compute theoretical image sensitivity,
- estimate the pipeline processing time,
- plot the elevation of the sources to observe on any given date,
- plan multi-beam observations, and
- export the observation and pipeline setup in a PDF format.

The landing page of the LUCI web interface is shown below in [Fig. 38](#). The page is divided into three columns each allowing the user to set a specific aspect of the observation. By setting different input fields, users can compute some or all of the parameters listed above. The different functionalities of LUCI are explained below.

LOFAR Unified Calculator for Imaging (LUCI)

Observational setup	Target setup	Results
Observation time (in seconds) 28800	Target RESOLVE	Theoretical image sensitivity (uJy/beam)
No. of core stations (0 - 24) 24	Coordinates 	Raw data size (in GB)
No. of remote stations (0 - 14) 14	Observation date 03/12/2019	Notes: The various features of this calculator are documented on the LOFAR Imaging Cookbook . The sensitivity calculation performed by this tool follow SKA Memo 113 by Nijboer, Pandey-Pommier & de Bruyn. It uses theoretical SEFD values. So, please use it with caution.
No. of international stations (0 - 14) 14	Calibrators Select...	
Number of channels per subband 64	A-team sources Select...	
Number of subbands 488	Pipeline setup	
Integration time (in seconds) 1	Pipeline None	
Antenna set HBA Dual In.		
CALCULATE GENERATE PDF		

Setting up an observation

The **Observational setup** section in LUCI allows users to specify an interferometric observing run with LOFAR. The various fields under this section are:

- **Observation time (in seconds)** – Duration of an observing run (default: 28800 seconds). LUCI throws an error if a negative value is provided as input.
- **No. of core stations (0 - 24)** (default: 24)
- **No. of remote stations (0 - 14)** (default: 14)
- **No. of international stations (0 - 14)** (default: 14)
- **Number of channels per subband** – Frequency resolution of an observing run. Allowed values are 64, 128, and 256 channels per subband (default: 64)
- **Number of subbands** – Number of subbands to record as part of the observing run (default: 488). LUCI throws an error if the number of subbands is greater than 488.
- **Integration time (in seconds)** - Correlator integration time. This input field determines the time resolution of the observing run (default: 1 second). LUCI throws an error if correlator time is smaller than 0.16 seconds.
- **Antenna set** – specifies the mode in which the stations are operated. Allowed values are LBA Outer, HBA Dual, and HBA Dual Inner. (default: HBA Dual Inner).

Upon clicking the button **Calculate**, LUCI computes the theoretical image sensitivity and the raw data size. The results of this computation is displayed to the user under the **Results** section. Note that before doing the calculations, LUCI validates the input specified by the user. If an invalid input is detected, LUCI displays an error as shown in Fig. 39.

The screenshot displays the LOFAR Unified Calculator for Imaging (LUCI) web interface. It is divided into three main sections: 'Observational setup', 'Target setup', and 'Results'. The 'Observational setup' section contains input fields for 'Observation time (in seconds)', 'No. of core stations (0 - 24)', 'No. of remote stations (0 - 14)', 'No. of international stations (0 - 14)', 'Number of channels per subband', 'Number of subbands', 'Integration time (in seconds)', and 'Antenna set'. The 'Target setup' section includes fields for 'Target', 'Coordinates', and 'Observation date', along with a 'RESOLVE' button. The 'Results' section shows 'Theoretical image sensitivity (uJy/beam)' and 'Raw data size (in GB)'. An error message dialog box is overlaid in the center, titled 'Error', with the text 'Observation time cannot be zero or negative.' and a 'CLOSE' button. The 'Observation time' field in the 'Observational setup' section is set to '-1'. The 'Antenna set' is set to 'HBA Dual Inner'. The 'Integration time' is set to '0.01'. The 'Number of subbands' is set to '488'. The 'Number of channels per subband' is set to '64'. The 'No. of core stations' is set to '24'. The 'No. of remote stations' is set to '14'. The 'No. of international stations' is set to '14'. The 'Target' field is empty. The 'Coordinates' field is empty. The 'Observation date' field is empty. The 'Pipeline' is set to 'None'. The 'Theoretical image sensitivity' and 'Raw data size' fields are empty. The 'Notes' section on the right contains text about the calculator's features, sensitivity calculation, and source code availability.

Fig. 39 Example error message displayed to the user. Before performing the calculations, LUCI validates the user input. If an invalid input is detected, LUCI shows a similar error message.

Setting up a preprocessing pipeline

Pipelines can be setup in LUCI using the field **Pipeline** dropdown button under **Pipeline setup**. At the moment, only a preprocessing pipeline can be specified. By default, no pipeline is attached to the observing run and hence the field **Pipeline** is set to None. To attach a preprocessing pipeline, set the **Pipeline** field to **Preprocessing**. Toggling the **Pipeline** field reveals a few more input fields (see [Fig. 40](#)) under **Pipeline setup** which can be used to tweak the behaviour of the pipeline. The new, pipeline-specific fields are

- **Time averaging factor** How much averaging to perform along the time axis (default: 1),
- **Frequency averaging factor** How much averaging to perform along the frequency axis (default: 1), and
- **Enable dysco compression?** Should the output measurement sets produced by the preprocessing pipeline be compressed with Dysco? (default: Enabled).

Upon clicking the **Calculate** button, LUCI calculates **Processed data size** and **Pipeline processing time** in addition to **Theoretical image sensitivity** and **Raw data size** mentioned earlier.

LOFAR Unified Calculator for Imaging (LUCI)

The screenshot displays the LUCI web interface, which is organized into three main columns: **Observational setup**, **Target setup**, and **Results**.

- Observational setup:** This column contains several input fields for observational parameters: Observation time (in seconds) set to 28800, No. of core stations (0 - 24) set to 24, No. of remote stations (0 - 14) set to 14, No. of international stations (0 - 14) set to 14, Number of channels per subband set to 64, Number of subbands set to 488, Integration time (in seconds) set to 0.01, and Antenna set set to HBA Dual In... At the bottom of this column are two buttons: **CALCULATE** and **GENERATE PDF**.
- Target setup:** This column includes a **Target** field with a **RESOLVE** button next to it, a **Coordinates** field, an **Observation date** field set to 03/12/2019, **Calibrators** and **A-team sources** dropdown menus, and a **Pipeline setup** section. The **Pipeline setup** section has a **Pipeline** dropdown menu set to **Preprocessing**, and three input fields: **Time averaging factor** (1), **Frequency averaging factor** (1), and **Enable dysco compression?** (Enable).
- Results:** This column displays the calculated results: **Theoretical image sensitivity (uJy/beam)** (10.34), **Raw data size (in GB)** (8349166), **Processed data size (in GB)**, and **Pipeline processing time (in hours)**. Below these results is a **Notes** section containing text about the calculator's documentation, the sensitivity calculation method (SKA Memo 113), and the tool's version (20191203) and maintenance information.

*Fig. 40 LUCI web interface showing the pipeline fields that are revealed when the field **Pipeline** is set to **Preprocessing**.*

Specifying targets, calibrators, and A-team sources

Besides calculating the data sizes and processing times, LUCI also allows users to check if their target of interest is visible to LOFAR on a specific date. The target of interest can be specified in the **Target** field under the **Target setup** section. If the specified source is valid, the **Resolve** button can be used to obtain the coordinates of that source. Note that LUCI can resolve valid

LoTSS pointing names as well (like P17 or P205+67). If however, the user wishes to manually input the coordinates, a target name must also be specified. The **Observation date** field allows the user to specify a date on which the target elevation needs to be calculated.

In addition to plotting the target, users can also plot the elevations of standard LOFAR calibrators and A-team sources by selecting them using the **Calibrators** and the **A-team sources** dropdown boxes.

Upon clicking the **Calculate** button, LUCI produces three plots like the once shown below:

- **Target visibility plot** shows the elevation of a target as seen by LOFAR on the specified date as an interactive plot. If the field **No. of international stations (0-14)** is set to 0 (i.e.) observing with only the Dutch array, the target elevation is calculated with respect to the LOFAR core. On the other hand, if the user specifies the full array, LUCI plots the minimum apparent elevation of the target as seen by all LOFAR stations. In addition to the user-specified target, LUCI also plots the elevations of the Sun, the Moon, and Jupiter by default. The two blue regions indicate the sunrise and sunset times.
- **Beam Layout** plots the tile and station beams for the specified observation.
- **Angular distance between specified target and other bright sources** table.

Fig. 41 LUCI web interface showing the target visibility and beam layout plots along with a table showing the angular distance between the specified target and known bright radio sources. Note that the target visibility plot shows the elevation of the Sun, the Moon and Jupiter in addition to the user-specified target. Also note that both the target visibility and beam layout plots are interactive plots.

Setting up multi-beam observations

To observe multiple sources with LOFAR simultaneously making use of its multi-beam capability, the user can specify multiple sources in the **Target** field as a comma-separated value. LUCI can handle coordinate resolution of both single and multiple sources. While specifying multiple sources, LUCI will throw an error if

- the number of sources mentioned in the **Target** field does not match the number of coordinates,
- the number of sources times the number of subbands is greater than 488. This is because any LOFAR observation cannot have more than 488 subbands.

Fig. 42 LUCI web interface showing the target visibility and beam layout plots along with a table showing the angular distance between the specified targets and known bright radio sources.

Exporting the setup

Users can export their “observational setup” to a PDF file using the **Generate PDF** button. Upon clicking the **Generate PDF** button, LUCI exposes the **Download file** link (see Fig. 43) below the two buttons which can be used to download the generated PDF file.

LOFAR Unified Calculator for Imaging (LUCI)

Fig. 43 LUCI web interface showing the PDF download link after a user clicks on the **Generate PDF** button.

Note that if you click on the **Generate PDF** button before using the **Calculate** button, LUCI will throw an error.

Frequently Asked Questions (FAQ)

In what framework is LUCI implemented?

LUCI is implemented using [Dash](#) which is a simple Python framework for building web applications. Interactive plotting is done using [Plotly](#).

Can I contribute to LUCI?

Sure! The source code of LUCI is available on [GitHub](#). If you have an interesting feature, feel free to submit a pull request to this repository.
